Date: 1405/07/18, 2026/10/10

Patient's Name: M.J

Responsible Physician: Dr. Ebrahimi

Patient Presentation:

A 40 Y/O woman with a known history of left breast cancer, previously treated with breast-conserving therapy (BCT) and adjuvant chemo-radiotherapy in 1400, presented with proven local recurrence involving the axillary and supraclavicular regions.

MRI studies demonstrate extensive involvement of the distal brachial plexus in the axillary region, with an approximately 4-cm segment affected. The tumor also infiltrates the distal portions of the subclavian vein and the proximal axillary vein, resulting in venous thrombosis secondary to tumor invasion.

Question:

What is the management plan?

Recommended Plan:

- ✓ MRI review confirmed distal brachial plexus involvement and thrombosis of the distal subclavian vein and proximal left axillary vein.
- ✓ The tumor is currently unrespectable; systemic therapy was recommended with ovarian suppression (OS) + aromatase inhibitor (AI) + CDK4/6 inhibitor.
